

malloc1.c

Accessing 1D array as if it
were a 2D.

$r = 3$ $c = 4$

currentRow = 1
currentCol = 2
total width = 4
"C" is the width

Formula: $(\text{currentRow} * \text{total width}) + \text{currentCol}$

$$(1 * 4) + 2 = 6$$

60

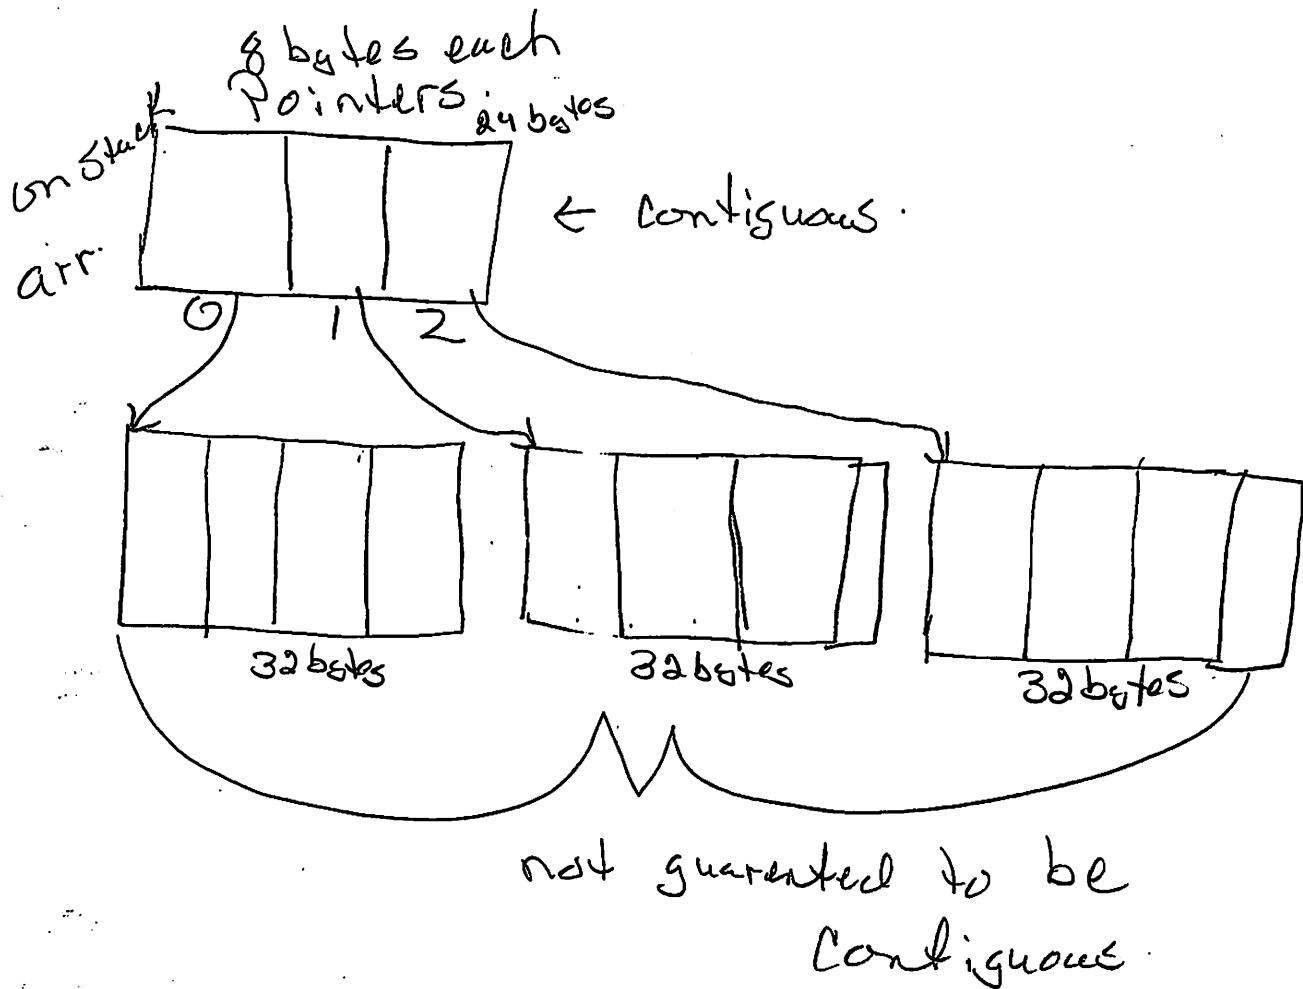

$\text{arr}[(\text{curr_row} * \text{total width}) + \text{curr_col}]$ is the same as
 $\text{arr}[(1 * 4) + 2]$ or $\text{arr}[6]$

malloc 2

$R=3$ $C=4$

`int *arr[R]`

Part is stored on stack & part
dynamically allocated.

malloc 4.c

2D Array using only 2 calls to malloc and 2 calls to free.

1st call to malloc allocates the memory for the pointers, 8 bytes each.

If the 1st for loop it starts at $arr[1]$ b/c $arr[0]$ is pointing to the allocated memory.

$(*arr + (C*i))$ calculates where in memory $arr[i]$ will point.

malloc4b.c - another way of allocating memory
for a 2D array. Uses only 1 malloc.

rows = 3 cols = 4

Calculate the memory needed for the pointers.

(12) header = $3 * \text{sizeof pointer} = 3 * 8 = 24 \text{ bytes}$

Calculate the amount of memory needed for the data.

(15) data = $3 * 4 * \text{sizeof int} = 3 * 4 * 4 = 48 \text{ bytes}$.

malloc the memory for the pointers & the data.

(17) malloc (72 bytes) $48 + 24$

$$\text{buffer} + (i * \text{cols}) = i = 0 \Rightarrow (0 * 4) = 0 = \text{buffer} + 0$$

$$\text{buffer} + (i * \text{cols}) = i = 1 \Rightarrow (1 * 4) = 4 = \text{buffer} + 4$$

$$\text{buffer} + (i * \text{cols}) = i = 2 \Rightarrow (2 * 4) = 8 = \text{buffer} + 8$$
